### Confessions of a pen tester

Typical scenario looks like this Customer calls and asks for a test 2-3 weeks prior to product going "live" Security test required by auditors Want to ensure "hackers can't get in" How secure are we?

What problems do you see here?

## The problem

Too many organizations have either:

- Neglected security testing entirely
- Assumed (incorrectly) their QA testing will catch security issues
- Adopted a late-cycle penetration test process as their sole security test

When you ask the wrong questions, you won't get the answers you need!

## Security testing is different

Security focus should primarily be on nonfunctional aspects of the software Not just focused on what the software can or should do Active deception of software intent Need to test every aspect of app

*QA team often has a tough time "thinking like an attacker"* 

## Uninformed "black box" testing

#### Advantages

- Unencumbered by prejudices of how things "should" behave
- Accurately emulates what an outsider might find
- Can be inexpensive and quick

#### Disadvantages

- Coverage is abysmal (10-20% LOC not abnormal)
- No notion of risk prioritization

# Informed testing

Advantages

- Effort can be allocated by risk priority
- Can ensure high coverage through careful test design

Emulate an insider attack

#### Disadvantages

Functional "blinders" might miss things

## **Testing methods**

Common practices include Fuzzing Penetration testing Dynamic validation Risk-based testing

# Fuzzing

Basic principle Hit software with random/ garbage Look for unanticipated failure states Observe and record Any good? MS estimates 20-25% of bugs found this way Watch for adequate coverage

## **Fuzzing techniques**

#### Smart fuzzing and dumb fuzzing

- "Dumb" refers to using random, unchosen data
- "Smart" implies using chosen garbage
- Example fuzzing a graphic renderer
  - Dumb approach is to throw it randomness
  - Smart approach is to study its expected file formats and to construct garbage that "looks" like what it expects, but isn't quite right

#### What to fuzz

Fuzz targets File fuzzing Network fuzzing Other I/O interfaces

Constructing "dumb" scenarios for each is easy, so let's look at some smart approaches

# File fuzzing

Smart scenarios

- Really study the expected file format(s)
- Look for things like parameters in data
- Construct nonsensical input data parameters
  - Negative or huge bitrate values for audio/video
  - Graphic dimensions

# Network fuzzing

#### Smart scenarios

- Really study the software-level network interfaces
  - Coverage here must include state
- Look for things like flags, ignoring state
- Also, HTTP/HTTPS interfaces
  - GET/POST
  - SOAP and RESTful interfaces too
    - Don't stop with the functions specified in the WSDL
- Construct nonsensical input data parameters
  - "Insane" packet sizes
  - Data overflows and underflows

# Interface fuzzing

Smart scenarios for all other "surfaces" Really study the data interfaces

- APIs, registry, environment, user inputs, etc.
- Construct nonsensical input data parameters
  - Overflows and underflows
  - Device names when file names are expected

## Automation is your friend...

...and your foe

Lots of fuzz products are appearing

How can one size possibly fit all?

How would you fuzz a browser Javascript (AJAX) function?

Best fuzzing tools are in fact frameworks

Examples OWASP's JBroFuzz, PEACH, SPI Fuzzer

## Finding value in pen testing

Enough with what's wrong

- Consider informed testing
- Quick form of attack resistance analysis
- **Risk-based** prioritization
- Nightmare scenarios from architectural risk analysis
- Abuse case stories
- Start with vendor tools, but then roll your sleeves up and do it yourself
  - Scripting tools can help tremendously

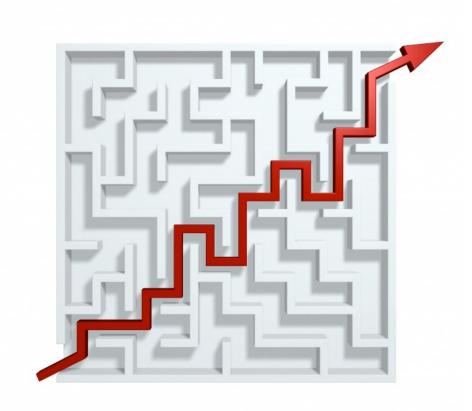

### Pen testing strategies

Inside => out approach is most likely to yield meaningful results

It doesn't hurt to also do an outside => in test

One very small part of overall testing

Adversarial approach Surprises happen

# Basic pen testing methods

Target scan

Take inventory of target space

Vulnerability scan

What potential preliminary weaknesses are present?

Vulnerability exploit

Attempt entry

Host-based discovery

What interesting "stuff" is on each breached system?

#### Recursive branching

Repeat until finished

### Pen test results

Results need to be actions for dev team Traditional pen test teams report to IT Need to adapt to different audience Map findings to modules and code

## Automation is really your friend

Pen test tool market is (arguably) one of the strongest in the security business

Choices abound in commercial and open source

Many are quite mature

Almost a commodity market

Examples include

Nmap, nessus, Metasploit, ISS, Core Impact, Retina

## **Dynamic validation**

- Time to verify all those security requirements and functional specs
  - QA will have easiest time building test cases with these
  - Fault injection often used
  - Helps if requirements verbiage is actionable
- Can also be driven by design
  - Look for key assumptions
    - E.g., "session token is always HTTPS"

### Automation, what's that?

#### Dearth of available tools

- Some process monitors are available and helpful
- Test cases are easiest to define

#### Specific tool hints

Web app proxies (work great with mobile apps too) Single stepping debuggers with key breakpoints MITM tools between app and OS

### **Risk-based testing**

Time to animate those "nightmare scenarios" you uncovered in the architectural risk analysis Start with abuse cases, weakness scenarios Describe and script them Try them one step at a time

Begin at the beginning and go on till you come to the end; then stop. – Lewis Carroll

### Automation, what's that?

Dearth of available tools

It's rare that these scenarios lend themselves to general purpose automation

Test cases are really tough to define

But many of same tools used in dynamic validation can be useful

### Additional considerations

There's plenty other things to think about Threat modeling Results tracking Five stages of grief Knowledge sharing Improvement and optimization

## Threat modeling can help drive

Who would attack us? What are their goals? What resources do they have? How will they apply technology? How much time do they have?

Answers can help in understanding feasibility of attacks

## **Results tracking**

- Lots of good reasons to track results
  - Use again during regression testing
  - Ensure closure
  - Knowledge transfer of lessons learned
  - Justify time spent

Tools can help Test Director

## Five stages of grief

Security testers are often the bearers of bad news Learn from the Kübler-Ross model

- Denial, anger, bargaining, depression, acceptance
- Watch out for denial and anger!
- Understand and anticipate

Diplomacy and tact will optimize likelihood of acceptance

# Knowledge sharing

Show the dev team how their code broke Best way to learn Learning from mistakes visually is hugely powerful

If a picture tells a thousand words, a live demonstration shows a thousand pictures

### Improvement and optimization

Immediate goal is to find defects in today's software, but preventing future defects is also a worthy goal

- Formalize lessons learned process
- Consider papers, blog entries, etc., to share new findings (once fixed) with others
- Learn from medical community model

## Getting started

Some general tips and guidelines Interface inventory Let risk be your navigator Get the right tools for the job Scripting skills can be very valuable

## Interface inventory

Start by enumerating every interface, API, input, output, etc.

- This should be done per module as well as per application
- List everything
- Some call this the "attack surface"
- This list should become a target list as you plan your tests
- Flow/architecture charts are useful

## **Risk navigation**

The target list is probably too big to do a thorough job

Prioritize focus in descending risk order

Follow the most sensitive data first

Those flow charts will set you free

See now why rigorous testing should be informed?

### Test scenario sources -1

#### Develop test scenarios throughout SDLC

- Start at requirements, such as
  - US regs: GLBA, SOX, HIPPA
  - ISO 17799 / BS 7799
  - PCI
  - OWASP's WASS
- Warning, they're often fuzzy (no pun...)
  - SOX says, "Various internal controls must be in place to curtail fraud and abuse."

### Test scenario sources -2

#### Also look elsewhere in SDLC for test cases

Abuse cases

• Many cases translate directly to test cases

Architectural risk analysis

• Seek the doomsday scenarios

Code

• Compliance with coding standards

## **Deployment testing**

Rigorous testing of environment Network services File access controls Secure build configurations Event logging Patch management Test for all of this • Not your job? Who is doing it? The pen testers?
